This high-throughput screen has been performed using our newly established (W.H.) and our previously reported (M.O.) cell-based assays as our first and second assays. We have analyzed DNA damage induced by more than 100 anticancer drugs including nucleoside analogs, alkylating agents, antimetabolites, antitumor antibiotics, and various other compounds. The drug-induced DNA damage was detected using the method previously developed for

our two-color screening of chemicals (I.W.) and the customized two-color technology using microarrays (M.O.), in order to perform a comparative study on the precision of this method. For the comparative study, the results of our newly established and our previously reported methods were statistically analyzed by comparison with the known results obtained by the comet assay. This comparative study clearly showed that the results of our previously reported method were highly correlated with the known values of the comet assay.
