Idiopathic scoliosis (IS) is a three-dimensional deformation of the spine. Although the true incidence of this deformity is unknown, one indication is that if 1 in 12,000 children had been examined in a period of 3 years, 700 would have been found to have the condition. In most cases, an 11 to 18 year old patient is affected. Apart from the fact that certain families have been shown to have a higher probability for the same mutation, probably due to environmental factors, no mechanism is known for its development. Clinical symptoms are mild at first and only become obvious later. The longitudinal curvature of the spine increases as the age of the patient advances, mainly to the right side, so that the thoracic curvature is more pronounced than the lumbar. Cobb's method of measuring a scoliosis was developed by Professor Robert A. Beachy in the 1920s. According to this method, an X-ray of the thoracic spine shows the position of the apical vertebra as the x-axis, the position of the vertebrae in front of and behind it as the y-axis, and the angle between the two as the z-axis. By using the coordinates, the position of all spinal units is determined and the angle of the spinal curvature can be calculated. This calculation is important for prediction of the curve's progress and determination of the prognosis. Unfortunately, the Cobb's method does not provide information about the true 6d1f23a050
